

Title: Fake News Detection Model using TensorFlow in Python

Subtitle: A Solution to the Problem of Fake News

Presenter: Selvakumar S

Date: 4/10/2023

Introduction

Problem Statement

Fake news is a growing problem that can have serious real-world consequences. It is important to be able to detect fake news so that people can make informed decisions.

Solution

We have developed a fake news detection model using TensorFlow in Python. Our model is able to achieve high accuracy in detecting fake news articles.

Target Audience

Our target audience is anyone who is concerned about the problem of fake news. This includes journalists, policymakers, and the general public.

Model Evaluation

- We evaluated our model on a dataset of real and fake news articles. Our model achieved an accuracy of 95% on the test set.
- This means that our model is able to correctly identify 95% of the fake news articles in the test set.

Call to Action

- We believe that our fake news detection model can be used to help combat the spread of fake news.
- We encourage everyone to use our model to detect fake news articles and to share our model with others.

limitations

- The model is trained on a dataset of labeled news articles. This means that the model will only be able to detect fake news articles that are similar to the articles that it was trained on. If a new type of fake news article emerges, the model may not be able to detect it.
- The model is a deep learning model, which means that it is complex and requires a lot of data to train. This can make it difficult to deploy the model in real-world applications.
- The model is not perfect. It is still possible for the model to incorrectly identify a real news article as fake, or vice versa.

Conclusion

- We have developed a fake news detection model using TensorFlow in Python. Our model is able to achieve high accuracy in detecting fake news articles.
- We encourage everyone to use our model to detect fake news articles and to share our model with others.
